

Term	Definition	Image
<b>App</b>	Short for application. A digital tool used on a smartphone or tablet to do a specific task.	
<b>Audiogram</b>	A graph of a person's hearing showing the quietest sound a person can hear (hearing threshold) at different frequencies of sound.	
<b>Audiometer</b>	Hearing test device used to measure hearing.	 Audiometer app on tablet
<b>Average hearing threshold</b>	A calculation adding threshold values of 500 Hz, 1000 Hz, 2000 Hz, and 4000 Hz then dividing by four.	
<b>Ear and hearing professional</b>	Professionals that test, manage, and treat ear and hearing problems.	
<b>Feedback (whistling)</b>	The “whistle” sound produced by the hearing aid when sound escapes from the ear and is picked up by the microphone of the hearing aid.	
<b>Frequency</b>	How many times a sound wave moves up and down in one second. There are different types of sound including deeper sounds (low frequency) such as a drum and sharper sounds (high frequency) such as a whistle. Frequency is measured in hertz (Hz).	
<b>Hearing threshold</b>	Quietest sound that the person can hear at different frequencies of sound.	
<b>Hertz (Hz)</b>	A way to measure how often something happens in one second. For example, if a sound wave vibrates 100 times in one second, it has a frequency of 100 Hz.	
<b>Ling sounds</b>	A set of six sounds. These cover the full range of speech sounds across low to high frequencies.	
<b>Prescriptive formula</b>	A calculation of the ideal amount of sound increase (amplification) applied at each frequency based on a person's hearing test results.	

<b>Standard earmould</b>	A ready-made shaped earpiece produced in different sizes to fit inside a person's ear. It connects to the hearing aid through a tube and delivers sound into a person's ear.	
<b>Stetoclip</b> (listening tube)	Also known as a listening tube, it allows a person with normal hearing to monitor if the hearing aid is working well.
